

Unilever plc — Argentina & Türkiye Hyperinflation Model

Hyperinflation Accounting Analysis — CFA LII Multinational Operations

Group Operating Profit (IFRS actual)	EUR 8,496.2m
Net Monetary Gain/(Loss)	EUR -195.0m
Earnings-Quality Signal	Flag: immaterial
Materiality Ratio	2.3%
As-of Year	2024

Investment Thesis

Unilever plc (LSE: ULVR) is a global consumer-goods group that reports under IFRS. Two of its operating subsidiaries sit in economies classified as hyperinflationary: Argentina (ARS, hyperinflationary since 1 July 2018) and Türkiye (TRY, since 1 July 2022). For both, Unilever restates the local accounts under IAS 29 into current purchasing power, then translates them at the closing rate under IAS 21. Each year it also reports how much that treatment moves the group's total assets, turnover and operating profit, along with the resulting net monetary gain/(loss), which makes it an unusually clean case study in how hyperinflation accounting flows through to group figures.

On the model's 2024 figures under the actual IFRS treatment, the modelled group has total assets of about €46,545m, revenue of about €60,845m and operating profit of about €8,496m. These totals use an illustrative rest-of-group scale, not Unilever's reported consolidated figures. Against that base, the hyperinflationary subsidiaries produce a combined net monetary loss of about €195m. Argentina's loss of about €206m more than accounts for it, and Türkiye partly offsets it with a gain of about €11m.

The model's earnings-quality read is **"Flag: immaterial"**. The net monetary loss is about **2.3% of group operating profit**, well below the model's 10% materiality threshold. Because the group base is illustrative, the ratio is indicative only. On this measure, the IAS 29 monetary effect does not move the needle at group level in 2024.

The tension this report explores is that the effect is dramatic at the subsidiary level: Argentina alone carries grade C on the model's A–F monetary-exposure scale, the weaker of the two subsidiary grades. It is less clear whether that should register as a group-level concern, or whether a roughly €195m item inside an €8.5bn operating-profit base is simply noise. The Bulls Say and Bears Say sections take up that question.

On market perception, public consensus (Stockopedia: Buy, target 5,287.14p against a 4,671.00p close on 28 September 2026; MarketScreener: 16 analysts, Outperform, target €61.43) shows no sign that it separates the IAS 29 net monetary gain/(loss) from ordinary FX translation. On earnings calls and in aggregator commentary, Argentina and Türkiye appear only as volume and pricing stories inside a generic aggregate "currency headwind". Paywalled broker notes could not be checked.

Bulls Say

- **The monetary hit is small next to group earnings.** The 2024 net monetary loss of about €195m is about 2.3% of group operating profit (€8,496m), well under the model's 10% materiality threshold. Colgate-Palmolive reached the same qualitative conclusion ("not expected to have a material impact") about its own highly-inflationary subsidiaries (Argentina, Türkiye and Nigeria), independently and under US GAAP.
- **Restatement barely moves reported operating profit.** Moving from plain current-rate translation (World A) to IAS 29 + IAS 21 (World C) adds about €417m of turnover, but restated costs absorb nearly all of it: COGS alone rises by about €255m. Operating profit ends only about €6m higher (€8,490m vs €8,496m). The headline profit line tells the same story under either treatment.
- **Türkiye is a small exposure.** Türkiye earns the model's top monetary-exposure grade (A), with a small net monetary *gain* of about €11m and an exposure ratio of just 2.6% on about €420m of subsidiary assets. The grade reflects a small net monetary gain relative to subsidiary assets (€10.999m on €419.82m), not hedging: the modelled subsidiary holds no protective assets. Only one of the two hyperinflationary subsidiaries is a real drag.
- **IFRS gives the less punitive result.** Under the IAS 29 treatment Unilever actually uses (World C), the net monetary loss is about €195m. The temporal-method alternative (World B) would show about €272m. World C also reports higher restated equity (about €20,785m vs €20,246m under World A) and lower leverage

(debt-to-equity 1.24x vs 1.27x).

- **Consensus remains constructive.** MarketScreener's consensus across 16 analysts is Outperform (target €61.43, range €45.65–€70.24), and Stockopedia's consensus target is 5,287.14p (+13.35% vs the 25 September 2026 close of 4,664.50p per the source; about +13.19% on our calculation vs the 28 September 2026 close of 4,671.00p). The market treats Argentina and Türkiye as growth stories: management cited "high single digit growth in Argentina" and strong performance in Turkey on the Q1 2026 call.

Bears Say

- **Argentina's modelled exposure is the weaker of the two and runs against intuition.** Argentina carries a monetary-exposure grade of C on the model's A–F scale, the weaker of the two subsidiary grades: a net monetary loss of about €206m on about €1,125m of subsidiary assets, an exposure ratio of about –18.3%. That single grade drags the group's overall grade down to C. In the model it books a loss despite sitting in a net monetary *liability* position, which should normally produce a gain. That position is a model output, solved from the balance-sheet plug given illustrative opening equity and monetary split, not a Unilever disclosure. The grade reflects the model's mechanics, not evidence about how management runs the balance sheet.

- **The 2024 tailwind reversed in 2025.** In 2024, local inflation outpaced FX depreciation, and the IAS 29 impact was positive (+€417m turnover, +€6m operating profit). In 2025, Argentina floated the peso and the lira kept sliding, and Unilever's disclosed impacts turned negative: Argentina –€54m and Türkiye –€46m operating profit, plus –€90m and –€16m turnover. Which way the effect runs depends on the macro regime, not on management.

- **The "immaterial" verdict rests on an illustrative model with known gaps.** The model's 2025 roll-forward misses the sign of total assets for both subsidiaries (Argentina +€184m modelled vs –€199m disclosed). It also overshoots Türkiye's net monetary line (–€113m modelled vs –€10m disclosed). The 2.3% materiality ratio is measured against an illustrative group scale, not Unilever's reported operating profit, so it is indicative only.

- **The market isn't looking at this line.** No public analyst commentary separates the IAS 29 net monetary gain/(loss) from ordinary FX. Currency is only discussed in aggregate: it cut H1 2026 turnover by 4.9% and underlying EPS growth by about 6 percentage points. Consensus is also less unanimous than the headline rating suggests: TipRanks' average of 5,148.89p includes 2 Sell ratings, and MarketScreener's range runs from €45.65 to €70.24. Paywalled broker notes could not be checked.

- **There is no exit in sight and no hedge.** Argentina has been hyperinflationary since July 2018. Türkiye remains classified that way on IAS 29's qualitative indicators even though headline inflation has eased toward about 31%, consistent with the IFRS Interpretations Committee's July 2025 agenda decision. Unlike BBVA, whose inflation-linked bonds offset €1,202m of its €2,118m 2023 Türkiye monetary loss, the modelled subsidiaries hold no protective assets. Restatement also inflates the asset base, trimming ROA to 18.25% under IAS 29 from 18.45% under World A.

Economic Moat

Moat Rating: Not assessed

This model contains no brand, scale or competitive-position analysis, so it does not rate Unilever's group-level moat. What it can say is that the hyperinflation data does not show a group-level problem: the combined net monetary loss of about €195m is only 2.3% of modelled group operating profit (€8,496m, an illustrative group scale rather than Unilever's reported figure, so the ratio is indicative only). The subsidiary-level figures below describe accounting exposure, not competitive position, so they do not support a local moat rating either.

The restatement says nothing about pricing power. Under IAS 29, 2024 turnover is about €417m higher than under World A, but operating profit is only about €6m higher. Restated COGS adds about €255m, and other costs absorb nearly all of the rest. Operating margin slips from 14.05% to 13.96%. That near-one-for-one offset is built into the model: revenue, COGS, opex and depreciation are all restated by the same in-year flow factor, so it is an artefact of the restatement, not evidence about whether Unilever's prices keep pace with local inflation. The same applies to Argentina's €230m turnover uplift becoming €10m of operating profit, and to Türkiye's €187m uplift coming with a €4m operating-profit *reduction*. In the 2025 disclosures, both operating-profit impacts turned clearly negative: Argentina –€54m and Türkiye –€46m. The model's 2025 macro assumptions have FX depreciation outpacing inflation, which would plausibly explain the reversal, but that is an assumption, not a disclosed fact.

Monetary-exposure grades differ sharply between the two. Argentina is graded **C**. Its net monetary loss of about €206m equals –18.3% of its €1,125m of total assets, even though the model has it in a net monetary *liability* position. Türkiye is graded **A**, with an exposure ratio of +2.6% (an €11m gain on €420m of assets). The overall grade is **C**. These grades reflect the model's mechanics, not evidence about how management runs either balance sheet: the subsidiary-level monetary-asset/liability split and opening equity are illustrative modelling choices calibrated to Unilever's disclosed aggregates, not reported figures.

Duration of exposure is not what drives the grades. Argentina has been hyperinflationary since July 2018 and Türkiye only since July 2022. The longer-running exposure shows the larger loss. That loss (Argentina's €206m) is Unilever's actual disclosed 2024 figure, which the calibration was solved to reproduce. Only the subsidiary asset base and monetary split behind the grades are illustrative, so the grades say nothing about any measured difference in how the two subsidiaries are managed.

Subsidiary-level figures are illustrative calibrations to Unilever's disclosed aggregates, not reported subsidiary accounts.

Valuation, Sensitivity & Scenarios

The three accounting worlds. The model presents Unilever's Argentina and Türkiye exposure under three accounting treatments. **World A** is the plain current-rate method with no inflation restatement. Historical-cost plant is translated at a collapsing closing rate, so it shrinks toward nothing in euro terms: the "disappearing plant" baseline. **World B** is the US GAAP temporal method, or remeasurement. Non-monetary items stay at historical FX, monetary items move to current FX, and the difference runs through income as a *remeasurement* gain or loss. **World C** is what Unilever actually reports under IFRS: IAS 29 restatement in local currency, followed by IAS 21 translation of everything at the closing rate. All three describe the same underlying economics under different accounting. They are not three valuations of the business, and this model does not attempt a DCF or multiples valuation.

The numbers. For 2024, World A and World B both show revenue of about €60,428m and operating profit of about €8,490m. World C shows revenue of €60,845m and operating profit of €8,496m. Total assets are €46,006m in World A, €46,108m in World B and €46,545m in World C. The net monetary line is nil in World A, a €272m remeasurement loss in World B, and a €195m IAS 29 net monetary loss in World C. The pattern is the one flagged in the model. World C adds about €417m of revenue and €539m of total assets compared with World A, but only about €6m of operating profit. Restating revenue and costs by the same inflation factor largely cancels at the profit line, even though the gross revenue and asset figures move a great deal.

IAS 29 impact by subsidiary. In 2024, restatement added €474m of total assets, €230m of turnover and €10m of operating profit in Argentina, with a €206m net monetary loss. In Türkiye it added €65m of total assets and €187m of turnover but *reduced* operating profit by €4m, and it produced an €11m net monetary gain.

Argentina's result goes against the textbook heuristic. The model's solved Argentine balance sheet is in a net monetary *liability* position, which the heuristic says should produce a gain, yet it books a loss. The monetary plug also nets against growth in restated opening equity and operating profit, and a fast-growing restated base can outweigh the real erosion of the liabilities. The simple rule is a starting intuition, not a formula that holds once the whole balance sheet is restated together.

2025 validation. The 2024 calibration was rolled forward to 2025 without re-fitting, and the result is only a partial match. For both subsidiaries, turnover, operating profit and net monetary gain/loss all have the same sign as Unilever's disclosures. Argentina's figures are –€31m, –€1m and –€24m in the model against –€90m, –€54m and –€46m disclosed. Türkiye's are –€47m, –€3m and –€113m against –€16m, –€46m and –€10m. The model undershoots both operating-profit lines and overshoots Türkiye's net monetary line roughly tenfold. Total assets do **not** match in sign: the model shows +€184m and +€46m, while Unilever disclosed –€199m and –€20m. This gap is structural. Restating non-monetary assets under a rising price index can only increase them, and World A and World C both use the same closing rate. The model's total-assets impact therefore cannot turn negative, and the disclosed negatives probably reflect disposals, impairments or a comparative-basis convention that the summary table does not show.

Peer comparison. Other companies disclose the same IAS 29 mechanics. Coca-Cola FEMSA reported an H1 2025 net monetary position gain of Ps.154m (up from Ps.42m), with the increase driven mainly by Argentine liabilities, a textbook case of liabilities eroded by inflation. BBVA's Türkiye (Garanti) net monetary loss of €2,118m in 2023 was partly offset by a separately disclosed €1,202m inflation-linked-bond gain, a hedge this model does not represent. The accounting regime also affects what gets disclosed. Colgate-Palmolive reports under US GAAP, the regime behind World B. It describes the effect of its highly inflationary designations as immaterial, past and expected, and discloses no dollar figure. That is the same "immaterial" conclusion this model reaches for Unilever (a €195m loss, about 2.3% of operating profit), reached independently under a different regime. Reckitt Benckiser, an IFRS filer like Unilever, reports the effect only inside a combined "exchange and hyperinflation" revenue item (£394m in 2025, £24m in 2024) that cannot be separated. Not every IFRS filer discloses at Unilever's level of detail.

Financial Health

Overall Grade: C

The grade comes from a simple rule that this model defines itself. It is not a Unilever-published or IFRS-defined scale. For each hyperinflationary subsidiary, the absolute net monetary gain/(loss) is divided by that subsidiary's total assets, and the result is mapped to a letter grade. The overall grade (C) matches Argentina's, the weaker of the two subsidiary grades.

- **Argentina: C.** Net monetary loss of €(206.0)m against total assets of €1,124.9m, an exposure ratio of (18.3)%.
- **Türkiye: A.** Net monetary gain of €11.0m against total assets of €419.8m, an exposure ratio of 2.6%.

Argentina alone pulls the overall grade down to C. Türkiye's grade reflects a small net monetary gain relative to its subsidiary assets (€11.0m on €419.8m). Argentina's net monetary loss is not small: it equals almost a fifth of the subsidiary's total assets. That loss does not come from a monetary position losing purchasing power. The model's solved Argentine balance sheet is in a net monetary *liability* position, which on the textbook heuristic should produce a gain. The loss arises because the monetary plug nets against growth in restated opening equity and operating profit. The grade therefore reflects the model's mechanics, not evidence about how Unilever actually manages the Argentine balance sheet: the subsidiary-level monetary split is an illustrative modelling choice calibrated to Unilever's disclosed aggregates, not a reported subsidiary balance sheet. At

group level the impact stays contained. The combined net monetary loss of €(195.0)m is about 2.3% of group operating profit of €8,496m (an illustrative group scale, not Unilever's reported consolidated figure), which the model flags as immaterial. The Argentina exposure is still the line to watch.

These grades are for **2024**, the primary calibrated year. For that year, the model's local-currency inputs were solved to reproduce Unilever's actual disclosed figures. The 2025 roll-forward is only a directional validation check and should not be read as a snapshot of the current position.

Market Consensus Comparison

Public sell-side consensus on Unilever (MarketScreener: 16 analysts, Outperform, target €61.43; Stockopedia: Buy, target 5,287.14p) sits alongside earnings calls that mention Argentina and Türkiye only as volume and pricing stories. On the Q1 2026 call, management treated them as volume stories, citing "high single digit growth in Argentina" and "strong performances in markets such as India, Turkey, and Vietnam". Currency came up only as one aggregate number: "FX reducing the reported turnover by 7.7%". On the Q2 2026 call, the one related analyst question treated hyperinflation as a Latin America pricing issue ("pricing was obviously flat in the quarter despite the hyperinflations..."). Management's answer again gave currency as one figure: a 4.9% hit to H1 turnover and roughly 6 points off underlying EPS growth.

None of this commentary separates the IAS 29 net monetary gain/(loss) from ordinary FX translation.

Both are folded into a generic "currency headwind". Unilever's own USG methodology also caps hyperinflationary price growth, which keeps the monetary line out of the headline growth metric. One caveat: paywalled broker notes (Deutsche Bank, Barclays, Bernstein) were not accessible.

At group level, this silence is roughly proportionate. The model's 2024 net monetary loss of €195m is about 2.3% of the €8,496m modelled operating profit, well below the 10% materiality threshold (the group base is an illustrative scale, not Unilever's reported figure, so the ratio is indicative only). The aggregate framing does understate how concentrated the exposure is, though. Argentina alone books a €206m loss, grades C on monetary exposure and has an exposure ratio of -18.3%. Türkiye's €11m gain (grade A) partly offsets it. Aggregate "FX" language on calls and in aggregator commentary hides that offset. The per-subsidiary split is disclosed in the Form 20-F hyperinflation note, but it is not what the market discusses, so it is easy to miss that a single subsidiary's loss is larger than the whole net effect.

Recommendation

Recommendation: Hold *(on the narrow question of whether the market misprices Unilever's IAS 29 hyperinflation effect; this is not a view on the stock as a whole)*

This model does not produce an intrinsic-value target price. It has no DCF or multiples build. The only question it answers is whether the hyperinflation accounting effect is a source of earnings-quality mispricing. The answer is no, for the following reasons.

1. The effect is immaterial at group level. In 2024 the net monetary loss was €-195m. Modelled group operating profit was €8,496m, so the loss is about 2.3% of operating profit. That is well below the 10% materiality threshold, and the mechanical signal is "**Flag: immaterial**". The Hold rating is this report's reading of that signal: an effect below the threshold gives no basis for a directional call. One caveat: the group base is an illustrative scale, not Unilever's reported consolidated figure, so the ratio is indicative only. An effect this small cannot move group earnings enough to support a directional view, however the market treats it.

2. Consensus does not separate the effect, but that doesn't matter here. Public aggregator and earnings-call transcript research found real consensus. MarketScreener shows 16 analysts at Outperform with

a target of €61.43; Stockopedia shows Buy with a target of 5,287.14p (no analyst count given) against a 4,671.00p close on 2026-09-28. The research also found no public evidence that analysts separate the IAS 29 net monetary gain/(loss) from ordinary FX translation. On the Q1 and Q2 2026 calls, Argentina and Türkiye came up as volume and pricing stories, and currency appeared only as one aggregate headwind. In this report's own judgement (not a rule set by the model, whose output is only the mechanical signal), this condition would support a Sell-leaning call **if the effect were material**. It isn't, so the market's blind spot costs little. A caveat: paywalled broker notes could not be checked.

3. What to watch. Argentina drives the exposure. It carries a grade-C monetary exposure (ratio -18.3%) and a €-206m net monetary loss, which is more than the whole group figure. Türkiye partly offsets it with a grade-A exposure and a €+11m gain. The 2025 validation matters for any future re-rating. Both subsidiaries' disclosed net monetary results are losses (Argentina €-46m, Türkiye €-10m), and the model gets the sign right but not the size. If the group net monetary loss, driven by Argentina, grew towards 10% of group operating profit (the materiality threshold) while consensus still folded it into generic "FX", then on this report's own reading (as described in point 2) the call would move from Hold towards a **Sell-leaning** call. Until then, there is no informational edge to act on.

Risks & Uncertainty

Argentina is the weak link. Argentina carries a monetary-exposure grade of C on the model's A–F scale, the weaker of the two subsidiary grades. In 2024 its net monetary loss was €206m, about 18% of its €1,125m total assets. The group ratio is small: net monetary loss of €195m against €8,496m operating profit, or 2.3%, below the 10% materiality threshold. Argentina alone more than accounts for it. Türkiye (grade A) booked a small €11m gain, about 2.6% of assets. A further Argentine inflation or FX shock hits this line directly.

The model is illustrative, not a reconstruction. The subsidiary inputs are fictional figures solved to reproduce Unilever's real 2024 disclosure (matched almost exactly). The 2025 out-of-sample test matched sign on only 3 of 4 lines per subsidiary; magnitudes missed: Türkiye's modelled net monetary loss was €113m against €10m disclosed, and Argentina's operating profit was –€1.4m against –€54m. The total-assets line cannot turn negative under this model's mechanics, yet real 2025 was –€199m for Argentina. Forward projections deserve far less confidence than the 2024 calibration. The 2.3% materiality ratio uses an illustrative group scale, not Unilever's reported consolidated figures.

The macro regime has already changed. 2024's positive impacts came from inflation (118% Argentina, 44% Türkiye) outpacing managed FX depreciation (~19%, ~18%). Argentina floated the peso in April 2025, and the lira kept depreciating while inflation slowed. Both plausibly reversed that relationship.

The market doesn't price this separately. Public transcripts and aggregators fold the net monetary line into a generic "currency" headwind; paywalled broker notes could not be checked. At today's immaterial scale that blind spot costs little, so consensus (target 5,287p vs 4,671p close) is not mispricing it. The risk is conditional: if the group net monetary loss, driven by Argentina, grew towards the 10%-of-operating-profit materiality threshold, the market's aggregate "FX" framing could leave it mispriced.

Classification could change. Türkiye's hyperinflationary status rests on IAS 29.3's qualitative indicators, not a bright-line test (IFRS Interpretations Committee, July 2025). Headline inflation has eased to ~31%. If Türkiye were reclassified, only its IAS 29 effect would disappear. Argentina's would remain, and losing Türkiye's €11m gain would slightly widen the group net monetary loss (from about €195m towards about €206m).
